AB Age-dependent changes in insulin action and body fat distribution are risk factors for the development of type 2 diabetes . To examine whether the accumulation of visceral fat (VF) could play a direct role in the pathophysiol. of insulin resistance and type 2 diabetes, we monitored insulin action, glucose tolerance, and the expression of adipo-derived peptides after surgical removal of VF in aging (20-mo-old) F344/Brown Norway (FBN) and in Zucker Diabetic Fatty (ZDF) rats. As expected, peripheral and hepatic insulin action were markedly impaired in aging FBN rats, and extraction of VF (accounting for .apprx.18% of their total body fat) was sufficient to restore peripheral and hepatic insulin action to the levels of young rats. When examined at the mechanistic level, removal of VF in ZDF rats prevented the progressive decrease in insulin action and delayed the onset of diabetes, but VF extraction did not alter plasma free fatty acid levels. However, the expression of tumor necrosis factor-a and leptin in s.c. (SC) adipose tissue were markedly decreased after VF removal (by approx. three- and twofold, resp.). Finally, extracted VF retained .apprx.15-fold higher resistin mRNA compared with SC fat. Our data suggest that insulin resistance and the development of diabetes can be significantly reduced in aging rats by preventing the age-dependent accumulation of VF. This study documents a cause-and-effect relationship between VF and major components of the metabolic syndrome.

AB Morbid obesity is the result of massive expansion of white adipose tissue (WAT) and requires recruitment of adipocyte precursor cells and their supporting infrastructure. To characterize the change in the expression profile of the preexisting WAT at the start of obesity , when adipocyte hypertrophy is present but hyperplasia is still minimal, the authors employed a cDNA subtraction screen for genes differentially expressed in epididymal fat pads harvested 1 wk after the start of a 60% fat diet. Ninety-six genes were upregulated by at least 50% above the WAT of control rats receiving a 4% fat diet. Of these genes, 30 had not previously been identified. Sixteen of the 96 genes, including leptin, adipocyte complement-related protein 30 kDa, and resistin, were predicted to encode a signal peptide. Ten of the 16 had been previously identified in other tissues and implicated in cell growth, proliferation, differentiation, cell cycle control, and angiogenesis. One was a novel gene. Twenty-nine novel fragments were identified. Thus, at the onset of high-fat-diet-induced obesity in rats, adipose tissue increases its expression of factors previously implicated in the expansion of non-adipocyte tissues and of several uncharacterized novel factors. The only one of these thus far characterized functionally was found to promote lipogenesis.

AB Plasma levels of the adipocyte product adiponectin, a putative insulin-sensitizing agent, are reduced in obesity, whereas plasma levels of resistin, an agent that some believe to confer insulin resistance, are thought to increase with obesity. Because adrenalectomy can increase insulin sensitivity, we hypothesized that adrenalectomy would increase expression of adiponectin and decrease expression of resistin. Therefore, we measured adiponectin mRNA, adiponectin peptide, and resistin mRNA in adrenalectomized ob/ob mice. Adrenalectomy restored adiponectin expression in ob/ob mice to wild-type levels and stimulated adiponectin peptide to above wild-type levels. Surprisingly, expression of adiponectin and resistin was highly positively correlated even after statistical removal of effects of insulin, glucose, and adiposity. In addition, adiponectin and resistin expression were also highly correlated in diet-induced obese mice. The data support a role for adiponectin in mediating some effects of adrenalectomy on insulin sensitivity.

AB Obesity-related insulin resistance is closely associated with visceral fat accumulation. Several adipocyte-secreted mols. have been implicated in the development of type 2 diabetes, among them, the recently discovered adiponectin and resistin proteins. Some of these adipocytokines are also present in the immune system, thus suggesting an intriguing functional connection. We determined adiponectin and resistin expressions in visceral (VAT) and s.c. adipose tissue of lean and obese Zucker (fa/fa) rats using reverse-transcription polymerase chain reaction. Moreover, we analyzed the variations after body-weight reduction in food-restricted obese rats. Resistin and adiponectin expression was significantly lower in VAT of genetically obese in comparison with lean rats; no differences were observed when s.c. adipose tissues of the same animals were compared. Weight loss resulted in an increase of adiponectin expression in VAT, whereas a further significant decrease in resistin mRNA level was observed Resistin is also present and equally expressed in splenocytes of lean and obese rats. Adiponectin and resistin are down-regulated in VAT of obese rats. Adiponectin expression is restored to normal levels after body-weight reduction, supporting its link with obesity -related insulin resistance. On the contrary, the further decrease of resistin mRNA after weight loss does not support the hypothesis that resistin may play a causative role in insulin resistance in obese rats. Moreover, we demonstrated the presence of resistin in immunocompetent cells in both humans and rats, thus adding another factor to the list of mols. that adipose tissue shares with the immune system.

AB A review. It is now widely accepted that white adipose tissue (WAT) secretes a number of peptide hormones, including leptin, several cytokines, adipsin and acylation-stimulating protein (ASP), angiotensinogen, plasminogen activator inhibitor-1 (PAI-1), adiponectin, resistin etc., and also produces steroids hormones. This newly discovered secretory function has shifted the authors' view of WAT, which is no longer considered only an energy storage tissue but a major endocrine organ, at the heart of a complex network influencing energy homeostasis, glucose and lipid metabolism, vascular homeostasis, immune response and even reproduction Virtually all known adipose secreted proteins are dysregulated when the WAT mass is markedly altered, either increased in the obese state or decreased in lipoatrophy. This strongly implicates adiposesecreted products in the ethiopathol. and/or complications of both obesity and cachexia. This review discusses the physiol. relevance of adipose secretion by focusing on protein and steroid hormones. Regulation of WAT secretion by the major regulatory factors impinging on the adipocytes, i.e., insulin, glucocorticoids, catecholamines and thiazolidinediones (TZD) will be addressed. The rationale for therapeutic strategies aimed at compensating adverse effects resulting from overprodn. or lack of a specific adipose secretory product will be discussed.

AB Adiponectin is a novel polypeptide that is highly specific to adipose tissue. In contrast to other adipocy-tokines, adiponectin levels are decreased in obesity and associated comorbidities, such as type 2 diabetes. Decreased expression of adiponectin is correlated with insulin resistance. It has been suggested that several agents, such as tumor necrosis factor a, could mediate their effects on insulin metabolism through modulating adiponectin secretion from adipocytes. The mechanisms for the development of atherosclerotic vascular disease in obese individuals are largely unknown. Several findings support the interesting hypothesis that adiponectin could be a link between obesity and related atherosclerosis. First, adiponectin levels are lower in patients with coronary artery disease. Second, adiponectin modulates endothelial function and has an inhibitory effect on vascular smooth muscle cell proliferation. Moreover, adiponectin is accumulated more preferably to the injured vascular wall than intact vessels and has been shown to suppress macrophage-to-foam cell transformation. Adiponectin may also be involved in the modulation of inflammation. Thiazolidinediones, antiatherogenic and other effects have been explained by their direct enhancing effect on adiponectin. In conclusion, adiponectin has anti-inflammatory and anti-atherogeneic effects as well as multiple beneficial effects on metabolism. Therefore it is not a surprise that adiponectin therapy has been tested in animal models of obesity, and it has been shown to ameliorate hyperglycemia and hyperinsulinemia without inducing weight gain or even inducing weight loss in some studies. Unlike agents that exert their effects centrally, adiponectin's effects seem to be peripherally mediated. The evidence of an association between adiponectin and the metabolic and cardiovascular complications of obesity is growing all the time.

AB Impaired fibrinolysis is a common finding in obese humans. This condition is now considered as an established risk factor for thromboembolic complications. Furthermore, obesity is characterized by a specific pattern of circulating concns. of fat-cell products interleukin-6 (IL-6), leptin, and adiponectin. The aim of our study was to investigate the relationship between these proteins and selected variables of the fibrinolytic system in 74 mildly hypertensive, overweight subjects. Circulating IL-6 and leptin levels showed a pos. association with BMI ($r = 0.24$, $p = 0.04$ and $r = 0.70$, $p < 0.0001$), whereas adiponectin was not correlated to BMI. Interestingly, IL-6 was also pos. associated with t-PA/PAI-1 complexes after adjustment for BMI and other anthropometric variables. Leptin was pos. correlated with PAI-1 activity and antigen ($r = 0.32$, $p = 0.006$ and $r = 0.37$, $p < 0.001$, resp.) and neg. with t-PA activity ($r = -0.27$, $p = 0.03$). However, these assocns. lost significance after correction for BMI or HOMA, an insulin

sensitivity index. In contrast, adiponectin levels were independently and neg. correlated with PAI-1 antigen (r = -0.26, p = 0.04, after correction for BMI). In conclusion, our study provides further evidence that IL-6, leptin, and adiponectin are associated with impaired fibrinolysis in overweight hypertensive humans.

AB Adipose tissue is a highly active endocrine organ secreting a range of soluble products with both local and distant actions. These hormones have important roles in metabolism, reproduction, cardiovascular function and immunity. It is now evident that adipose endocrine function directly influences other organ systems, including the brain, liver and skeletal muscle. The endocrine function of adipose tissue is significantly regulated by nutritional status, and both are inextricably linked to the energy storage role of adipose tissue. This chapter highlights the endocrinology of adipose tissue by concentrating on functional aspects of the secreted products. The data of particular relevance to humans are highlighted, and areas in need of future research are suggested. .COPYRGT. 2002 Elsevier Science Ltd. All rights reserved.

AB Abdominal obesity has been linked to the development of insulin resistance and Type 2 diabetes mellitus (DM2). By surgical removal of visceral fat (VF) in a variety of rodent models, we prevented insulin resistance and glucose intolerance, establishing a cause-effect relationship between VF and the metabolic syndrome. To characterize the biol. differences between visceral and peripheral fat depots, we obtained perirenal visceral (VF) and s.c. (SC) fat from 5 young rats. We extracted mRNA from the fat tissue and performed gene array hybridization using Affymetrix technol. with a platform containing 9000 genes. Out of the 1660 genes that were expressed in fat tissue, 297 (17.9%) genes show a two-fold or higher difference in their expression between the two tissues. We present the 20 genes whose expression is higher in VF fat (by 3-7 fold) and the 20 genes whose expression is higher in SC fat (by 3-150 fold), many of which are predominantly involved in glucose homeostasis, insulin action, and lipid metabolism We confirmed the findings of gene array expression and quantified the changes in expression in VF of genes involved in insulin resistance (PPARg leptin) and its syndrome (angiotensinogen and plasminogen activating inhibitor-1, PAI-1) by real-time PCR (qRT-PCR) technol. Finally, we demonstrated increased expression of resistin in VF by around 12-fold and adiponectin by around 4-fold, peptides that were not part of the gene expression platform. These results indicate that visceral fat and s.c. fat are biol. distinct.

AB The mechanisms underlying obesity and type 2 diabetes remain to be elucidated. Two novel adipose-derived cytokines, resistin and adiponectin, have been implicated in these processes. The purpose of this study was to determine the expression of resistin and adiponectin in lean and fatty Zucker rats over a range of ages. Animals (n=9-10/group) were euthanized at 6, 7, 10, and 14 weeks of age and epididymal white adipose tissue was collected. The results showed that the fatty rats weighed significantly more, had greater adipose tissue mass as well as higher levels of plasma leptin, insulin, free-fatty acids, and triglycerides ($p<0.05$). Within each age class, the expression of resistin and adiponectin was reduced in the fatty compared to the lean Zucker rats ($p<0.05$). Our results are in agreement with recently published data suggesting that the expression of resistin and adiponectin is reduced with obesity and increasing insulin resistance.

AB We compared the decrease in insulin resistivity in obese patients with diabetes using the insulin resistance index (HOMA-R) and the physiol. active substances secreted by adipose tissue (LPL mass, leptin, adiponectin). Changes in the homologous levels were investigated at the same time. As the HOMA-R progressed, leptin became

kinetic and adiponectin increased, showing an antagonistic relationship. As for the adipocytokine correlation, in the group with a BMI exceeding 25 kg/m2, correlations of BMI vs. leptin (r = 0.694, p = 0.0003) and adiponectin vs. LPL mass (r = 0.618, p <0.0022) were recognized, and the same when compared with the group in which HOMA-R was over 2.0. From these results, insulin resistivity showed a characteristic morbid condition.

AB A review. It is widely accepted that increasing adiposity is associated with insulin resistance and increased risk of type 2 diabetes. The predominant paradigm used to explain this link is the portal/visceral hypothesis. This hypothesis proposes that increased adiposity, particularly in the visceral depots, leads to increased free fatty acid flux and inhibition of insulin action via Randle's effect in insulin-sensitive tissues. Recent data do not entirely support this hypothesis. As such, two new paradigms have emerged that may explain the established links between adiposity and disease. Three lines of evidence support the ectopic fat storage syndrome. First, failure to develop adequate adipose tissue mass in either mice or humans, also known as lipodystrophy, results in severe insulin resistance and diabetes. This is thought to be the result of ectopic storage of lipid into liver, skeletal muscle, and the pancreatic insulin-secreting beta cell. Second, most obese patients also shunt lipid into the skeletal muscle, the liver, and probably the beta cell. The importance of this finding is exemplified by several studies demonstrating that the degree of lipid infiltration into skeletal muscle and liver correlates highly with insulin resistance. Third, increased fat cell size is highly associated with insulin resistance and the development of diabetes. Increased fat cell size may represent the failure of the adipose tissue mass to expand and thus to accommodate an increased energy influx. Taken together, these three observations support the acquired lipodystrophy hypothesis as a link between adiposity and insulin resistance. The endocrine paradigm developed in parallel with the ectopic fat storage syndrome hypothesis. Adipose tissue secretes a variety of endocrine hormones, such as leptin, interleukin-6, angiotensin II, adiponectin (also called ACRP30 and adipoQ), and resistin. From this viewpoint, adipose tissue plays a critical role as an endocrine gland, secreting numerous factors with potent effects on the metabolism of distant tissues. These two new paradigms provide a framework to advance our understanding of the pathophysiol. of the insulin-resistance syndrome.

AB A review. Adipocytes have traditionally been considered to be the primary site for whole body energy storage mainly in the form of triglycerides and fatty acids. This occurs through the ability of insulin to markedly stimulate both glucose uptake and lipogenesis. Conventional wisdom held that defects in fuel partitioning into adipocytes either because of increased adipose tissue mass and/or increased lipolysis and circulating free fatty acids resulted in dyslipidemia, obesity, insulin resistance and perhaps diabetes. However, it has become increasingly apparent that loss of adipose tissue (lipodystrophies) in both animal models and humans also leads to metabolic disorders that result in severe states of insulin resistance and potential diabetes. These apparently opposite functions can be resolved by the establishment of adipocytes not only as a fuel storage depot but also as a critical endocrine organ that secretes a variety of signaling mols. into the circulation. Although the mol. function of these adipocyte-derived signals are poorly understood, they play a central role in the maintenance of energy homeostasis by regulating insulin secretion, insulin action, glucose and lipid metabolism, energy balance, host defense and reproduction The diversity of these secretory factors include enzymes (lipoprotein lipase (LPL) and adipsin), growth factors [vascular endothelial growth factor (VEGF)], cytokines (tumor necrosis factor-a, interleukin 6) and several other hormones involved in fatty acid and glucose metabolism (leptin, Acrp30,

resistin and acylation stimulation protein). Despite the large number of mols. secreted by adipocytes, our understanding of the pathways and mechanisms controlling intracellular trafficking and exocytosis in adipocytes is poorly understood. In this article, we will review the current knowledge of the trafficking and secretion processes that take place in adipocytes, focusing our attention on two of the best characterized adipokine mols. (leptin and adiponectin) and on one of the most intensively studied regulated membrane proteins, the GLUT4 glucose transporter.

AB Circulating adiponectin levels fall, whereas leptin levels rise with obesity, suggesting that regulation of these two adipocyte-derived hormones may be simultaneously influenced by common obesity-related factors. The authors examined adiponectin mRNA levels in WAT and in some instances, brown adipose tissue (BAT) following fasting and refeeding, acute and chronic administration of a b3-adrenergic agonist, acute treatment with retinoic acid (RA) and a glucocorticoid, and following chronic infusion of leptin and compared the expression of adiponectin to that of leptin in each circumstance. Serum concns. of adiponectin were also reported for most of the treatments. Fasting diminished and refeeding reversed both adiponectin and leptin gene expression. Peripheral injection of the b3-adrenergic agonist, CL316,243, suppressed both leptin and adiponectin expression in WAT. A small but significant reduction in adiponectin expression in BAT was also observed following this treatment. Although CL316,23 lowered serum leptin levels markedly, it did not affect serum adiponectin levels. A chronic 7-day infusion of CL316,243 resulted in an elevation of adiponectin expression in WAT and serum concns. in contrast to suppressions in both mRNA and serum levels of leptin by a similar treatment as previously reported. Chronic administration of leptin did not alter adiponectin synthesis in WAT compared to controls, but prevented the reduction in adiponectin synthesis associated with pair feeding. Food restriction through pair feeding also diminished adiponectin expression in BAT. Collectively, although leptin and adiponectin are inversely correlated with obesity, leptin does not appear to participate directly in adiponectin synthesis. The short-term regulation of the two adipokine expression in WAT is somewhat similar, perhaps subjective to common control of energy balance. The long-term regulation of adiponectin expression in WAT appears to be the opposite of that of leptin and may be more sensitive to changes in adiposity or insulin sensitivity.

AB Potent activation of PPAR gamma by thiazolidinediones(TZD) increases TG content of WAT, thereby decreasing TG content of liver/muscle, leading to amelioration of insulin resistance at the expense of obesity.
Moderate reduction of PPAR gamma activity by PPAR gamma/RXR inhibitors decreases TG content of WAT/muscle/liver due to increased leptin and increase in fatty-acid combustion and decrease in lipogenesis, thereby ameliorating HF diet-induced obesity and insulin resistance.
Moreover, PPAR gamma/RXR inhibitors decrease lipogenesis in WAT, while TZD stimulate adipocyte differentiation and apoptosis, thereby both preventing adipocyte hypertrophy, which is associated with alleviation of insulin resistance presumably due to decreases in FFA, and TNF alpha, and upregulation of adiponectin. We conclude that although by different mechanisms, both PPAR gamma/RXR inhibitors and PPAR gamma agonist improve insulin resistance, which is associated with decreased TG content of muscle/liver and prevention of adipocyte hypertrophy.

AB Adiponectin is an adipocyte-derived hormone. Recent genome-wide scans have mapped a susceptibility locus for type 2 diabetes and metabolic syndrome to chromosome 3q27, where the gene encoding adiponectin is located. Here we show that decreased expression of adiponectin correlates with insulin resistance in mouse models of altered insulin sensitivity. Adiponectin decreases insulin resistance by decreasing triglyceride content in muscle and liver in obese mice. This effect results from increased expression of molecules involved in both fatty-acid combustion and energy dissipation in muscle. Moreover, insulin resistance in lipoatrophic mice was completely reversed by the combination of physiological doses of adiponectin and leptin, but only partially by either adiponectin or leptin alone. We conclude that decreased adiponectin is implicated in the development of insulin resistance in mouse models of both obesity and lipoatrophy. These data also indicate that the replenishment of adiponectin might provide a novel treatment modality for insulin resistance and type 2 diabetes.

AB The traditional role attributed to white adipose tissue is energy storage, fatty acids being released when fuel is required. The metabolic role of white fat is, however, complex. For example, the tissue is needed for normal glucose homeostasis and a role in inflammatory processes has been proposed. A radical change in perspective followed the discovery of leptin; this critical hormone in energy balance is produced principally by white fat, giving the tissue an endocrine function. Leptin is one of a number of proteins secreted from white adipocytes, which include angiotensinogen, adipsin, acylation-stimulating protein, adiponectin, retinol-binding protein, tumour neorosis factor alpha, interleukin 6, plasminogen activator inhibitor-1 and tissue factor. Some of these proteins are inflammatory cytokines, some play a role in lipid metabolism, while others are involved in vascular haemostasis or the complement system. The effects of specific proteins may be autocrine or paracrine, or the site of action may be distant from adipose tissue. The most recently described adipocyte secretory proteins are fasting-induced adipose factor, a fibrinogen-angiopoietin-related protein, metallothionein and resistin. Resistin is an adipose tissue-specific factor which is reported to induce insulin resistance, linking diabetes to obesity. Metallothionein is a metal-binding and stress-response protein which may have an antioxidant role. The key challenges in establishing the secretory functions of white fat are to identify the complement of secreted proteins, to establish the role of each secreted protein, and to assess the pathophysiological consequences of changes in adipocyte protein production with alterations in adiposity (obesity, fasting, cachexia). There is already considerable evidence of links between increased production of some adipocyte factors and the metabolic and cardiovascular complications of obesity. In essence, white adipose tissue is a major secretory and endocrine organ involved in a range of functions beyond simple fat storage.

AB Adiponectin is a novel, adipose-specific protein abundantly present in the circulation, and it has antiatherogenic properties. We analyzed the plasma adiponectin concentrations in age- and body mass index (BMI)-matched nondiabetic and type 2 diabetic subjects with and without coronary artery disease (CAD). Plasma levels of adiponectin in the diabetic subjects without CAD were lower than those in nondiabetic subjects (6.6+-0.4 versus 7.9+-0.5 mug/mL in men, 7.6+-0.7 versus 11.7+-1.0 mug/mL in women; P<0.001). The plasma adiponectin concentrations of diabetic patients with CAD were lower than those of diabetic patients without CAD (4.0+-0.4 versus 6.6+-0.4 mug/mL, P<0.001 in men; 6.3+-0.8 versus 7.6+-0.7 mug/mL in women). In contrast, plasma levels of leptin did not differ between diabetic patients with and without CAD. The presence of microangiopathy did not affect the plasma adiponectin levels in diabetic patients. Significant, univariate, inverse correlations were observed between adiponectin levels and fasting plasma insulin (r=-0.18, P<0.01) and glucose (r=-0.26, P<0.001) levels. In multivariate analysis, plasma insulin did not independently affect the plasma adiponectin levels. BMI, serum triglyceride concentration, and the presence of diabetes or CAD remained significantly related to plasma adiponectin concentrations. Weight reduction significantly elevated plasma adiponectin levels in the diabetic subjects as well as the nondiabetic subjects. These results suggest that the decreased plasma adiponectin concentrations in diabetes may be an indicator of macroangiopathy.

AB Peroxisome proliferator-activated receptor gamma (PPARgamma) is a ligand-activated transcription factor and functions as a heterodimer with a retinoid X receptor (RXR). Supraphysiological activation of PPARgamma by thiazolidinediones can reduce insulin resistance and hyperglycemia in type 2 diabetes, but these drugs can also cause weight gain. Quite unexpectedly, a moderate reduction of PPARgamma activity observed in heterozygous PPARgamma-deficient mice or the Pro 12 Ala polymorphism in human PPARgamma has been shown to prevent insulin resistance and obesity induced by a high-fat (HF) diet. We investigated whether functional antagonism toward PPARgamma/RXR could be used to treat obesity and type 2 diabetes. We show herein that moderate reduction of PPARgamma with an RXR antagonist or a PPARgamma antagonist decreases triglyceride (TG) content in white adipose tissue, skeletal muscle and liver. These inhibitors potentiate leptin's effects and stimulated adiponectin levels, which increases fatty acid combustion and energy dissipation, thereby ameliorating HF diet-induced obesity and insulin resistance. Paradoxically, severe reduction of PPARgamma by treatment of heterozygous PPARgamma-deficient mice with an RXR antagonist or a PPARgamma antagonist depletes white adipose tissue and markedly decreases leptin and adiponectin levels and energy dissipation, which increases TG content in skeletal muscle and the liver, thereby leading to the re-emergence of insulin resistance. Our data suggest that appropriate functional antagonism of PPARgamma/RXR may be a logical approach to protection against obesity and related diseases such as type 2 diabetes.

AB A review with 49 refs. Adipose tissue is a source of passively stored excess energy. Adipose tissue has been found to secrete various biol. active adipocytokines such as leptin, plasminogen activator inhibitor (PAI)-1 and tumor necrosis factor (TNF) a, which affect homeostasis throughout the body. Plasma adipocytokines increase in obesity and the accumulation of fat, especially visceral fat, may serve to create greater insulin resistance or thrombotic tendency in obesity, through enhanced secretion of the above compds. In search for genes expressed in adipose tissue, novel adipose-specific genes, adiponectin and aquaporin adipose were isolated in the present study. Adiponectin had a collagen-like sequence and was secreted into blood. Plasma adiponectin paradoxically decreased in obesity, but was expressed exclusively in adipose tissue. Aquaporin adipose is also highly expressed in adipose tissue. This new water channel transports glycerol as well as water, suggesting aquaporin adipose to possibly be essential to glycerol metabolism in adipocytes. The finding of genes specifically expressed in visceral fat and new adipocytokines should facilitate clarification of the mechanism for the development and complications of visceral fat accumulation.

AB A review, with 12 refs. Obesity is a major cause of common human disorders including diabetes mellitus, hyperlipidemia, hypertension, and atherosclerotic vascular disease. Recent studies on adipocyte biol. have revealed that adipose tissue is not simply an energy storage organ but also an endocrine organ secreting a variety of bioactive substances called "adipocytokines" which affect biol. function of each target organ. For example, TNF-a from adipose tissues is one of the key factors for the development of insulin resistance. Leptin is another famous adipocytokines, which have an important role in controlling appetite and energy expenditure. To clarify the mol. characteristics of adipose tissue, a systemic anal. of expressed genes was performed using large-scale-random sequencing and revealed that adipose tissue, especially visceral adipose tissue expressed numerous genes for secretory proteins (.apprx.30% and .apprx.20% of the total genes in visceral and s.c. adipose tissue, resp.). Among these secretory proteins, active genes reputedly related to atherogenesis such as plasminogen activator inhibitor-1 (PAI-1) and heparin-binding EGF-like growth factor (HB-EGF) were found in the library. PAI-1, a regulator of fibrinolytic system, was overexpressed in the visceral adipose tissue in an animal model of obesity. Plasma levels of PAI-1 were closely correlated with visceral adiposity in human subjects. A novel adipose-specific collagen-like mol. named adiponectin was found. This novel mol. is suggested to have an anti-atherogenic property such as inhibition of smooth muscle cell proliferation and inhibition of adhesion mol. expression in endothelial cells, etc. The plasma levels of adiponectin unlike leptin were neg. correlated with body mass indexes. Thus, adipose tissue acts as an endocrine organ secreting a variety of bioactive substances, adipocytokines. Hypersecretion of adipocytokines such as PAI-1 or TNF-a and hyposecretion of those such as adiponectin in obese state may relate to the pathogenesis of obesity-related diseases including diabetes mellitus and vascular disease.

AB Age-dependent changes in insulin action and body fat distribution are risk factors for the development of type 2 diabetes . To examine whether the accumulation of visceral fat (VF) could play a direct role in the pathophysiol. of insulin resistance and type 2 diabetes, we monitored insulin action, glucose tolerance, and the expression of adipo-derived peptides after surgical removal of VF in aging (20-mo-old) F344/Brown Norway (FBN) and in Zucker Diabetic Fatty (ZDF) rats. As expected, peripheral and hepatic insulin action were markedly impaired in aging FBN rats, and extraction of VF (accounting for .apprx.18% of their total body fat) was sufficient to restore peripheral and hepatic insulin action to the levels of young rats. When examined at the mechanistic level, removal of VF in ZDF rats prevented the progressive decrease in insulin action and delayed the onset of diabetes, but VF extraction did not alter plasma free fatty acid levels. However, the expression of tumor necrosis factor-a and leptin in s.c. (SC) adipose tissue were markedly decreased after VF removal (by approx. three- and twofold, resp.). Finally, extracted VF retained .apprx.15-fold higher resistin mRNA compared with SC fat. Our data suggest that insulin resistance and the development of diabetes can be significantly reduced in aging rats by preventing the age-dependent accumulation of VF. This study documents a cause-and-effect relationship between VF and major components of the metabolic syndrome.

AB Adiponectin, also referred to as AdipoQ or ACRP30, is a plasma protein produced and secreted exclusively from adipose tissue. The protein contains a collagen-like domain and a C1q-like globular domain. A protease-generated globular segment enhances fatty acid oxidation in muscles, thereby modulating lipid and glucose metabolism. Plasma adiponectin levels are inversely correlated with the severity of insulin resistance. A recent genome-wide scan study mapped a susceptibility locus for type 2 diabetes and the metabolic syndrome to chromosome 3q27, where the adiponectin gene is located. Here, we screened Japanese patients with type 2 diabetes and age- and BMI-matched nondiabetic control subjects for mutations in adiponectin gene. We identified four missense mutations (R112C, I164T, R221S, and H241P) in the globular domain. Among these mutations, the frequency of I164T mutation was significantly higher in type 2 diabetic patients than in age- and BMI-matched control subjects ($P < 0.01$). Furthermore, plasma adiponectin concentrations of subjects carrying I164T mutation were lower than those of subjects without the mutation. All the subjects carrying I164T mutation showed some feature of metabolic syndrome, including hypertension, hyperlipidemia, diabetes, and atherosclerosis. Our findings suggest that I164T mutation is associated with low plasma adiponectin concentration and type 2 diabetes.

AB A review. It is now widely accepted that white adipose tissue (WAT) secretes a number of peptide hormones, including leptin, several cytokines, adipsin and acylation-stimulating protein (ASP), angiotensinogen, plasminogen activator inhibitor-1 (PAI-1), adiponectin, resistin etc., and also produces steroids hormones. This newly discovered secretory function has shifted the authors' view of WAT, which is no longer considered only an energy storage tissue but a major endocrine organ, at the heart of a complex network influencing energy homeostasis, glucose and lipid metabolism, vascular homeostasis, immune response and even reproduction Virtually all known adipose secreted proteins are dysregulated when the WAT mass is markedly altered, either increased in the obese state or decreased in lipoatrophy. This strongly implicates adiposesecreted products in the ethiopathol. and/or complications of both obesity and cachexia. This review discusses the physiol. relevance of adipose secretion by focusing on protein and steroid hormones. Regulation of WAT secretion by the major regulatory factors impinging on the adipocytes, i.e., insulin, glucocorticoids, catecholamines and thiazolidinediones (TZD) will be addressed. The rationale for therapeutic strategies aimed at compensating adverse effects resulting from overprodn. or lack of a specific adipose secretory product will be discussed.

AB A review. Adiponectin is a recently identified adipose tissue-derived protein (adipocytokine) with important metabolic effects. It is exclusively expressed in adipose tissue and released into the circulation. Adiponectin expression and/or secretion is increased by insulin like growth factor-1 and ionomycin, and decreased by tumor necrosis factor-a, glucocorticoids, b-adrenergic agonists and cAMP. Data for insulin are somewhat inconclusive. Moreover, adiponectin expression and secretion are increased by activators of peroxisome proliferator-activated receptor (PPAR)-g. Besides inhibiting inflammatory pathways, recombinant adiponectin increases insulin sensitivity and improves glucose tolerance in various animal models. This insulin-sensitizing effect appears to be mostly attributable to enhanced suppression of glucose production, but beneficial effects on muscle cannot be excluded. In humans, plasma adiponectin concns. exceed those of any other hormone by a thousand times; they decrease with obesity and are pos. associated with whole-body insulin sensitivity. Therefore, low adiponectin may contribute to the decrease in whole-body insulin sensitivity that accompanies obesity. Furthermore, there is increasing evidence that genetic variants in the adiponectin gene itself and/or in genes encoding adiponectin-regulatory proteins - such as PPAR-g - may be associated with hypoadiponectinemia, insulin resistance and type 2 diabetes. This suggests that adiponectin may reflect PPAR-g activity in vivo. Finally, reversal or alleviation of hypoadiponectinemia may represent a target for development of drugs improving insulin sensitivity and glucose tolerance.

AB A review. It is widely accepted that increasing adiposity is associated with insulin resistance and increased risk of type 2 diabetes. The predominant paradigm used to explain this link is the portal/visceral hypothesis. This hypothesis proposes that increased adiposity, particularly in the visceral depots, leads to increased free fatty acid flux and inhibition of insulin action via Randle's effect in insulin-sensitive tissues. Recent data do not entirely support this hypothesis. As such, two new paradigms have emerged that may explain the established links between adiposity and disease. Three lines of evidence support the ectopic fat storage syndrome. First, failure to develop adequate adipose tissue mass in either mice or humans, also known as lipodystrophy, results in severe insulin resistance and diabetes. This is thought to be the result of ectopic storage of lipid into liver, skeletal muscle, and the pancreatic insulin-secreting beta cell. Second, most obese patients also shunt lipid into the skeletal muscle, the liver, and probably the beta cell. The importance of this finding is exemplified by several studies demonstrating that the degree of lipid infiltration into skeletal muscle and liver correlates highly with insulin resistance. Third, increased fat cell size is highly associated with insulin resistance

and the development of diabetes. Increased fat cell size may represent the failure of the adipose tissue mass to expand and thus to accommodate an increased energy influx. Taken together, these three observations support the acquired lipodystrophy hypothesis as a link between adiposity and insulin resistance. The endocrine paradigm developed in parallel with the ectopic fat storage syndrome hypothesis. Adipose tissue secretes a variety of endocrine hormones, such as leptin, interleukin-6, angiotensin II, adiponectin (also called ACRP30 and adipoQ), and resistin. From this viewpoint, adipose tissue plays a critical role as an endocrine gland, secreting numerous factors with potent effects on the metabolism of distant tissues. These two new paradigms provide a framework to advance our understanding of the pathophysiol. of the insulin-resistance syndrome.

AB A review. Adipocytes have traditionally been considered to be the primary site for whole body energy storage mainly in the form of triglycerides and fatty acids. This occurs through the ability of insulin to markedly stimulate both glucose uptake and lipogenesis. Conventional wisdom held that defects in fuel partitioning into adipocytes either because of increased adipose tissue mass and/or increased lipolysis and circulating free fatty acids resulted in dyslipidemia, obesity, insulin resistance and perhaps diabetes. However, it has become increasingly apparent that loss of adipose tissue (lipodystrophies) in both animal models and humans also leads to metabolic disorders that result in severe states of insulin resistance and potential diabetes. These apparently opposite functions can be resolved by the establishment of adipocytes not only as a fuel storage depot but also as a critical endocrine organ that secretes a variety of signaling mols. into the circulation. Although the mol. function of these adipocyte-derived signals are poorly understood, they play a central role in the maintenance of energy homeostasis by regulating insulin secretion, insulin action, glucose and lipid metabolism, energy balance, host defense and reproduction The diversity of these secretory factors include enzymes (lipoprotein lipase (LPL) and adipsin), growth factors [vascular endothelial growth factor (VEGF)], cytokines (tumor necrosis factor-a, interleukin 6) and several other hormones involved in fatty acid and glucose metabolism (leptin, Acrp30, resistin and acylation stimulation protein). Despite the large number of mols. secreted by adipocytes, our understanding of the pathways and mechanisms controlling intracellular trafficking and exocytosis in adipocytes is poorly understood. In this article, we will review the current knowledge of the trafficking and secretion processes that take place in adipocytes, focusing our attention on two of the best characterized adipokine mols. (leptin and adiponectin) and on one of the most intensively studied regulated membrane proteins, the GLUT4 glucose transporter.

AB Obesity which is defined as accumulation of excess body fat, is a major cause of atherosclerotic vascular disease in industrial countries. Recent advances in the biology of adipose tissue have revealed that adipose tissue is not simply an energy storage organ but it also secretes a variety of molecules which affect the metabolism of the whole body. Through a systematic search of active genes in adipose tissue, we found that adipose tissue, especially visceral fat expressed numerous genes for secretory proteins (about 30% of total genes analyzed). Among them, plasminogen activator-1 (PAI-1), which is a regulator of the fibrinolytic system, was overexpressed in the visceral fat in an animal model of obesity. Plasma levels of PAI-1 were closely correlated with visceral fat adiposity. Thus, PAI-1 secreted from visceral fat may play some role in thrombotic vascular disease in visceral obesity. Adiponectin, a novel adipose-specific gene product, which has a matrix-like structure, is abundantly present in the bloodstream. Dysregulated secretion of adiponectin may be related to vascular disease in obesity. Biologically active molecules secreted from adipose tissue (adipocytokines) may have important roles in the development of atherosclerotic disease in obesity.
